Problem: Feedback Linearization

Feedback Linearization

0.0/15.0 points (graded)

True or false: for any underactuated system of the form $\ddot{\mathbf{q}} = \mathbf{f}_1(\mathbf{q}, \dot{\mathbf{q}}) + \mathbf{f}_2(\mathbf{q}, \dot{\mathbf{q}}) \mathbf{u}$, one can choose $\mathbf{u}(\mathbf{x}, \mathbf{u}')$ so that $\dot{\mathbf{x}} = \mathbf{A}\mathbf{x} + \mathbf{B}\mathbf{u}'$, where \mathbf{u}' is a new control input.

☐ True

☒ False ✓

Take a robot whose dynamics are given by the manipulator equations,

$\mathbf{H}(\mathbf{q}) \ddot{\mathbf{q}} + \mathbf{C}(\mathbf{q}, \dot{\mathbf{q}}) \dot{\mathbf{q}} + \mathbf{G}(\mathbf{q}) = \mathbf{B}(\mathbf{q}) \mathbf{u}$ for $\mathbf{q} \in \mathbb{R}^n$. The robot starts in a given initial configuration $\mathbf{q}(0) = \mathbf{q}_0$ and with a given initial velocity $\dot{\mathbf{q}}(0) = \dot{\mathbf{q}}_0$. Suppose $\mathbf{B}(\mathbf{q})$ is rank n for all \mathbf{q} . Which of the following statements are true for **any** twice-differentiable desired trajectory $\mathbf{q}_d : \mathbb{R} \rightarrow \mathbb{R}^n$?

- a. Feedback linearization can be used to make it so that $\mathbf{q}(t) = \mathbf{q}_d(t)$ for all $t \geq 0$
- b. Feedback linearization can be used to make it so that $\dot{\mathbf{q}}(t) = \dot{\mathbf{q}}_d(t)$ for all $t \geq 0$
- c. Feedback linearization can be used to make it so that $\ddot{\mathbf{q}}(t) = \ddot{\mathbf{q}}_d(t)$ for all $t \geq 0$

☐ a

☐ b

☒ c ✓

Explanation

Feedback linearization of a second-order system can create arbitrary accelerations $\ddot{\mathbf{q}}$, however, it cannot change the simple fact that we are dealing with a second-order system. Position and velocity are still limited in important, fundamental ways--particularly, both must be differentiable with respect to time. On the other hand, $\ddot{\mathbf{q}}$ has no such restriction, it can, and often will be, discontinuous in time.

Oscillating Pendulum

Consider an actuated pendulum, where the base is forced to oscillate in simple harmonic motion, $C \sin(\omega t)$. Then, the dynamics of the pendulum angle θ are:

$$\ddot{\theta} = \frac{g}{l} \sin \theta - \frac{C}{l} \omega^2 \sin(\omega t) \sin \theta + \frac{u}{ml^2}$$

Even with the base shaking, we would like the pendulum to spin at a constant speed, $\dot{\theta} = 1$. To achieve this, we should choose $\ddot{\theta}_{des}$ to stabilize any velocity error. Use feedback linearization to find the control law such that $\ddot{\theta} = -\dot{\theta} + 1$. Write the variable v for $\dot{\theta}$.

Trigonometric functions and greek letters can be written out in English, and should format properly. For example, simply write "sin(omega*t)" to form $\sin(\omega t)$

$u =$

Answer: $m \cdot l^2 \cdot (-v + 1 - g/l \cdot \sin(\theta) + C/l \cdot \omega^2 \cdot \sin(\omega t) \cdot \sin(\theta))$

Explanation

Substituting the desired behavior, $(\ddot{\theta} = -\dot{\theta} + 1)$ into the dynamic equation above, we can rearrange and solve for u ,

$$u = ml^2 (1 - v) - mgl \sin(\theta) + mlC\omega^2 \sin(\omega t) \sin \theta$$
